## Slot-queue - An optimized wait-free distributed MPSC

#### 1. Motivation

A good example of a wait-free MPSC has been presented in [1]. In this paper, the authors propose a novel tree-structure and a min-timestamp scheme that allow both enqueue and dequeue to be wait-free and always complete in  $\Theta(\log n)$  where n is the number of enqueuers.

We have tried to port this algorithm to distributed context using MPI. The most problematic issue was that the original algorithm uses load-link/ store-conditional (LL/SC). To adapt to MPI, we have to propose some modification to the original algorithm to make it use only compare-and-swap (CAS). Even though the resulting algorithm pretty much preserve the original algorithm's characteristic, i.e. wait-freedom and time complexity of  $\Theta(\log n)$ , we have to be aware that this is  $\Theta(\log n)$ remote operations, which is very expensive. We have estimated that for an enqueue or a dequeue operation in our initial LTQueue version, there are about  $2 * \log n$  to  $10 * \log n$  remote operations, depending on data placements and the current state of the LTQueue.

Therefore, to be more suitable for distributed context, we propose a new algorithm that's inspired by LTQueue, in which both enqueue and dequeue only perform a constant number of remote operations, at the cost of dequeue having to perform  $\Theta(n)$  local operations, where n is the number of enqueuers. Because remote operations are much more expensive, this might be a worthy tradeoff.

#### 2. Structure

Each enqueuer will have a local SPSC as in LTQueue [1] that supports dequeue, enqueue and readFront. There's a global array whose entries store the minimum timestamp of the corresponding enqueuer's local SPSC.

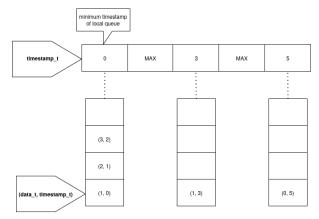

Figure 1: Basic structure of slot queue

#### 3. Pseudocode

#### 3.1. **SPSC**

The SPSC of [1] is kept in tact, except that we change it into a circular buffer implementation.

#### Types

```
data_t = The type of data stored
spsc_t = The type of the local SPSC
    record
    First: int
    Last: int
    Capacity: int
    Data: an array of data_t of capacity
    Capacity
    end
```

#### Shared variables

First: index of the first undequeued entry Last: index of the first unenqueued entry

#### Initialization

```
First = Last = 0
Set Capacity and allocate array.
```

The procedures are given as follows.

Procedure 1: spsc\_enqueue(v: data\_t) returns bool

- 1 if (Last + 1 == First)
  2 | return false
- 3 Data[Last] = v
- 4 Last = (Last + 1) % Capacity
- 5 return true

Procedure 2: spsc\_dequeue() returns data\_t

- 6 **if** (First == Last) **return**  $\perp$
- 7 res = Data[First]
- 8 First = (First + 1) % Capacity
- 9 return res

Procedure 3: spsc readFront returns data t

- 10 if (First == Last)
- 11 | return  $\perp$
- 12 return Data[First]

#### 3.2. Slot-queue

The slot-queue types and structures are given as follows:

#### **Types**

data\_t = The type of data stored
timestamp\_t = uint64\_t
spsc\_t = The type of the local SPSC

#### Shared variables

slots: An array of timestamp\_t with the number of entries equal the number of enqueuers spscs: An array of spsc\_t with the number of entries equal the number of enqueuers counter: uint64\_t

#### **Initialization**

| Initialize all local SPSCs.

Initialize slots entries to MAX.

The enqueue operations are given as follows:

Procedure 4: enqueue(rank: int, v: data\_t)
returns bool

- 1 timestamp = FAA(counter)
- 2 value = (v, timestamp)
- 3 res = spsc\_enqueue(spscs[rank], value)
- 4 if (!res) return false
- 5 if (!refreshEnqueue(rank, timestamp))
- 6 | refreshEnqueue(rank, timestamp)
- 7 return res

Procedure 5: refreshEnqueue(rank: int, ts:
timestamp\_t) returns bool

- 8 old-timestamp = slots[rank]
- 9 front = spsc\_readFront(spscs[rank])
- new-timestamp = front ==  $\bot$  ? MAX : front.timestamp
- 11 if (new-timestamp != ts)
- 12 | return true
- return CAS(&slots[rank], old-timestamp,
  new-timestamp)

The dequeue operations are given as follows:

#### Procedure 6: dequeue() returns data\_t

- 14 rank = readMinimumRank()
- 15 if (rank == DUMMY || slots[rank] == MAX)
- 16 | return ⊥
- 17 res = spsc\_dequeue(spscs[rank])
- 18 **if** (res ==  $\perp$ ) **return**  $\perp$
- 19 if (!refreshDequeue(rank))
- 20 | refreshDequeue(rank)
- 21 return res

#### Procedure 7: readMinimumRank() returns int

```
22 rank = length(slots)
23 min-timestamp = MAX
24 for index in 0..length(slots)
     timestamp = slots[index]
     if (min-timestamp < timestamp)</pre>
26
       rank = index
2.7
       min-timestamp = timestamp
28
29 \text{ old-rank} = \text{rank}
30 for index in 0..old-rank
     timestamp = slots[index]
31
     if (min-timestamp < timestamp)
32
       rank = index
33
       min-timestamp = timestamp
  return rank == length(slots) ? DUMMY :
35
   rank
```

## Procedure 8: refreshDequeue(rank: int) returns bool

```
36 old-timestamp = slots[rank]
37 front = spsc_readFront(spscs[rank])
38 new-timestamp = front == \(\perp \)? MAX :
front.timestamp
39 return CAS(&slots[rank], old-timestamp,
new-timestamp)
```

# 4. Linearizability of the local SPSC

In this section, we prove that the local SPSC is linearizable.

**Lemma 4.1** (*Linearizability of spsc\_enqueue*) The linearization point of spsc\_enqueue is right after line 2 or right after line 4.

**Proof** Notice that only spsc\_enqueue can modify the Last shared variable and only spsc\_dequeue can modify the First shared variable.

If line 2 is executed, that means Last + 1 == First and the enqueue is deemed as failed. This

state can only be exited when an spsc\_dequeue executes line 8. If line 2 is executed before line 8 of spsc\_dequeue then it's safe that we linearize spsc\_enqueue before spsc\_dequeue. Therefore, line 2 is a linearization point of spsc\_enqueue.

Suppose line 2 is not executed.

If line 4 hasn't been executed, the SPSC is as if no element has been enqueued. On the other hand, if line 4 is executed, the enqueue is sure to have completed and other spsc\_dequeues or spsc\_readFront can see this enqueue's effect. Therefore, line 4 is another linearization point of spsc\_enqueue.

**Lemma 4.2** (*Linearizability of spsc\_dequeue*) The linearization point of spsc\_dequeue is right after line 6 or right after line 8.

**Proof** Notice that only spsc\_enqueue can modify the Tail shared variable and only spsc\_dequeue can modify the Head shared variable.

If line 6 is executed, that means Last == First and the dequeue is deemed as failed. This state can only be exited when an spsc\_enqueue executes line 4. If line 6 is executed before line 4 of spsc\_dequeue then it's safe that we linearize spsc\_dequeue before spsc\_enqueue. Therefore, line 6 is a linearization point of spsc\_enqueue.

Suppose line 6 is not executed.

If line 8 hasn't been executed, the SPSC is as if no element has been dequeued. On the other hand, if line 8 is executed, the dequeue is sure to have completed and other spsc\_enqueue or spsc\_readFront can see this enqueue's effect. Therefore, line 8 is another linearization point of spsc\_enqueue.

**Lemma 4.3** (*Linearizability of spsc\_readFront*) The linearization point spsc\_readFront is right after line 11 or right after line 12.

**Proof** If line 11 is executed, that means spsc\_readFront has just observed and effect of line 8 of spsc\_dequeue or has not observed line 4 of spsc\_enqueue. In this case, spsc\_readFront

is linearized after this spsc\_dequeue or before spsc\_enqueue.

If line 12 is executed, that means spsc\_readFront has just observed and effect of line 4 of spsc\_enqueue or has not observed line 8 of spsc\_dequeue. In this case, spsc\_readFront is linearized after this spsc\_enqueue or before spsc\_dequeue.

**Theorem 4.4** (*Linearizability of local SPSC*) The local SPSC is linearizable.

**Proof** This directly follows from Lemma 4.1, Lemma 4.2, Lemma 4.3.

### 5. ABA problem

Noticeably, we use no scheme to avoid ABA problem in Slot-queue. In actuality, ABA problem does not adversely affect our algorithm's correctness, except in the extreme case that the 64-bit global counter overflows, which is unlikely.

#### 5.1. ABA-safety

Not every ABA problem is unsafe. We formalize in this section which ABA problem is safe and which is not.

**Definition 5.1.1** A **modification instruction** on a variable v is an atomic instruction that may change the value of v e.g. a store or a CAS.

**Definition 5.1.2** A successful modification instruction on a variable v is an atomic instruction that changes the value of v e.g. a store or a successful CAS.

**Definition 5.1.3** A **CAS-sequence** on a variable v is a sequence of instructions of a method m such that:

- The first instruction is a load  $v_0 = load(v)$ .
- The last instruction is a CAS(&v,  $v_0$ ,  $v_1$ ).
- There's no modification instruction on v between the first and the last instruction.

**Definition 5.1.4** A successful CAS-sequence on a variable v is a CAS-sequence on v that ends with a successful CAS.

**Definition 5.1.5** Consider a method m on a concurrent object S. m is said to be **ABA-safe** if and only if for any history of method calls produced from S, we can reorder any successful CAS-sequences by an invocation of m in the following fashion:

- If a successful CAS-sequence is part of an invocation of m, after reordering, it must still be part of that invocation.
- If a successful CAS-sequence by an invocation of m precedes another in that same invocation, after reordering, this ordering is still respected.
- Any successful CAS-sequence by an invocation of m after reordering must not overlap with a successful modification instruction on the same variable.
- After reordering, all method calls' response events on the concurrent object *S* stay the same.

#### 5.2. Proof of ABA-safety

Notice that we only use CASes on:

- Line 13 of refreshEnqueue (Procedure 5), which is part of an enqueue in general (Procedure 4).
- Line 42 of refreshDequeue (Procedure 8), which is part of a dequeue in general (Procedure 6).

Both CASes target some slot in the slots array.

We apply some domain knowledge of our algorithm to the above formalism.

**Definition 5.2.1** A **CAS-sequence** on a slot s of an enqueue that corresponds to s is the sequence of instructions from line 8 to line 13 of its refreshEnqueue.

**Definition 5.2.2** A **slot-modification instruction** on a slot s of an enqueue that corresponds to s is line 13 of refreshEnqueue.

**Definition 5.2.3** A **CAS-sequence** on a slot s of a dequeue that corresponds to s is the sequence of instructions from line 36 to line 39 of its refreshDequeue.

**Definition 5.2.4** A **slot-modification instruction** on a slot s of a dequeue that corresponds to s is line 39 of refreshDequeue.

**Definition 5.2.5** A **CAS-sequence** of a dequeue/ enqueue is said to **observe a slot value of**  $s_0$  if it loads  $s_0$  at line 8 of refreshEnqueue or line 36 of refreshDequeue.

We can now turn to our interested problem in this section.

**Lemma 5.2.1** (Concurrent accesses on a local SPSC and a slot) Only one dequeuer and one enqueuer can concurrently modify a local SPSC and a slot in the slots array.

**Proof** This is trivial to prove based on the algorithm's definition.  $\Box$ 

**Lemma 5.2.2** (Monotonicity of local SPSC timestamps) Each local SPSC in Slot-queue contains elements with increasing timestamps.

Proof Each enqueue would FAA the global counter (line 1 in Procedure 4) and enqueue into the local SPSC an item with the timestamp obtained from the counter. Applying Lemma 5.2.1, we know that items are enqueued one at a time into the SPSC. Therefore, later items are enqueued by later enqueues, which obtain increasing values by FAA-ing the shared counter. The theorem holds. □

**Lemma 5.2.3** A refreshEnqueue (Procedure 5) can only change a slot to a value other than MAX.

**Proof** For refreshEnqueue to change the slot's value, the condition on line 11 must be false. Then new-timestamp must equal to ts, which is not MAX. It's obvious that the CAS on line 13 changes the slot to a value other than MAX.

**Theorem 5.2.4** (ABA safety of dequeue) Assume that the 64-bit global counter never overflows, dequeue (Procedure 6) is ABA-safe.

**Proof** Consider a **successful CAS-sequence** on slot s by a dequeue d.

Denote  $t_d$  as the value this CAS-sequence observes.

Due to Lemma 5.2.1, there can only be at most one enqueue at one point in time within d.

If there's no successful slot-modification instruction on slot s by an enqueue e within d's successful CAS-sequence, then this dequeue is ABA-safe.

Suppose the enqueue e executes the last successful slot-modification instruction on slot s within d's successful CAS-sequence. Denote  $t_e$  to be the value that e sets s.

If  $t_e \neq t_d$ , this CAS-sequence of d cannot be successful, which is a contradiction.

Therefore,  $t_e = t_d$ .

Note that e can only set s to the timestamp of the item it enqueues. That means, e must have enqueued a value with timestamp  $t_d$ . However, by definition,  $t_d$  is read before e executes the CAS. This means another process (dequeuer/enqueuer) has seen the value e enqueued and CAS s for e before  $t_d$ . By Lemma 5.2.1, this "another process" must be another dequeuer d' that precedes d because it overlaps with e.

Because d' and d cannot overlap, while e overlaps with both d' and d, e must be the *first* enqueue on s that overlaps with d. Combining with Lemma 5.2.1 and the fact that e executes the *last* successful slot-modification instruction on slot s within d's successful CAS-sequence, e must be the only enqueue that executes a successful slot-modification instruction on s within d's successful CAS-sequence.

During the start of *d*'s successful CAS-sequence till the end of *e*, spsc\_readFront on the local SPSC must return the same element, because:

- There's no other dequeues running during this time.
- There's no enqueue other than *e* running.
- The spsc\_enqueue of e must have completed before the start of d's successful CAS sequence, because a previous dequeuer d' can see its effect.

Therefore, if we were to move the starting time of d's successful CAS-sequence right after e has

ended, we still retain the output of the program because:

- The CAS sequence only reads two shared values: slots[rank] and spsc\_readFront(), but we have proven that these two values remain the same if we were to move the starting time of d's successful CAS-sequence this way.
- The CAS sequence does not modify any values except for the last CAS instruction, and the ending time of the CAS sequence is still the same.
- The CAS sequence modifies slots[rank] at the CAS but the target value is the same because inputs and shared values are the same in both cases.

We have proved that if we move *d*'s successful CAS-sequence to start after the *last* **successful slot-modification instruction** on slot s within *d*'s **successful CAS-sequence**, we still retain the program's output.

If we apply the reordering for every dequeue, the theorem directly follows.  $\Box$ 

**Theorem 5.2.5** (ABA safety of enqueue) Assume that the 64-bit global counter never overflows, enqueue (Procedure 4) is ABA-safe.

**Proof** Consider a **successful CAS-sequence** on slot s by an enqueue e.

Denote  $t_e$  as the value this CAS-sequence observes.

Due to Lemma 5.2.1, there can only be at most one enqueue at one point in time within e.

If there's no successful slot-modification instruction on slot s by a dequeue d within e's successful CAS-sequence, then this enqueue is ABA-safe.

Suppose the dequeue d executes the last successful slot-modification instruction on slot s within e's successful CAS-sequence. Denote  $t_d$  to be the value that d sets s.

If  $t_d \neq t_e$ , this CAS-sequence of e cannot be successful, which is a contradiction.

Therefore,  $t_d = t_e$ .

If  $t_d=t_e=$  MAX, this means e observes a value of MAX before d even sets s to MAX. If this MAX value is the initialized value of s, it's a contradiction, as s must be non-MAX at some point for a dequeue such as d to run. If this MAX value is set by an enqueue, it's also a contradiction, as refreshEnqueue cannot set a slot to MAX. Therefore, this MAX value is set by a dequeue d'. If  $d'\neq d$  then it's a contradiction, because between d' and d, s must be set to be a non-MAX value before d can be run. Therefore, d'=d. But, this means e observes a value set by d, which violates our assumption.

Therefore  $t_d=t_e=t'\neq {\rm MAX}.\ e$  cannot observe the value t' set by d due to our assumption. Suppose e observes the value t' from s set by another enqueue/dequeue call other than d.

If this "another call" is a dequeue d' other than d, d' precedes d. By Lemma 5.2.2, after each dequeue, the front element's timestamp will be increasing, therefore, d' must have set s to a timestamp smaller than  $t_d$ . However, e observes  $t_e = t_d$ . This is a contradiction.

Therefore, this "another call" is an enqueue e' other than e and e' precedes e. We know that an enqueue only sets s to the timestamp it obtains.

Suppose e' does not overlap with d. e' can only set s to t' if e' sees that the local SPSC has the front element as the element it enqueues. Due to Lemma 5.2.1, this means e' must observe a local SPSC with only the element it enqueues. Then, when d executes readFront, the item e' enqueues must have been dequeued out already, thus, d cannot set s to t'. This is a contradiction.

Therefore, e' overlaps with d.

For  $e^\prime$  to set s to the same value as d,  $e^\prime$ 's spsc\_readFront must serialize after d's spsc\_dequeue.

Because e' and e cannot overlap, while d overlaps with both e' and e, d must be the *first* dequeue on s that overlaps with e. Combining with Lemma 5.2.1

and the fact that d executes the *last* successful slot-modification instruction on slot s within e's successful CAS-sequence, d must be the only dequeue that executes a successful slot-modification instruction within e's successful CAS-sequence.

During the start of e's successful CAS-sequence till the end of d, spsc\_readFront on the local SPSC must return the same element, because:

- There's no other enqueues running during this time.
- There's no dequeue other than *d* running.
- The spsc\_dequeue of d must have completed before the start of e's successful CAS sequence, because a previous enqueuer e' can see its effect.

Therefore, if we were to move the starting time of e's successful CAS-sequence right after d has ended, we still retain the output of the program because:

- The CAS sequence only reads two shared values: slots[rank] and spsc\_readFront(), but we have proven that these two values remain the same if we were to move the starting time of e's successful CAS-sequence this way.
- The CAS sequence does not modify any values except for the last CAS/store instruction, and the ending time of the CAS sequence is still the same.
- The CAS sequence modifies slots[rank] at the CAS but the target value is the same because inputs and shared values are the same in both cases.

We have proved that if we move *e*'s successful CAS-sequence to start after the *last* **successful slot-modification instruction** on slot s within *e*'s **successful CAS-sequence**, we still retain the program's output.

If we apply the reordering for every enqueue, the theorem directly follows.  $\Box$ 

**Theorem 5.2.6** (ABA safety) Assume that the 64-bit global counter never overflows, Slot-queue is ABA-safe.

**Proof** This follows from Theorem 5.2.5 and Theorem 5.2.4.

## 6. Linearizability of Slot-queue

**Definition 6.1** For an enqueue or dequeue op, rank(op) is the rank of the enqueuer whose local SPSC is affected by op.

**Definition 6.2** For an enqueuer whose rank is r, the value stored in its corresponding slot at time t is denoted as slot(r,t).

**Definition 6.3** For an enqueuer with rank r, the minimum timestamp among the elements between First and Last in its local SPSC at time t is denoted as min-spsc-ts(r,t).

**Definition 6.4** For an enqueue, **slot-refresh phase** refer to its execution of line 5-6 of Procedure 4.

**Definition 6.5** For a dequeue, **slot-refresh phase** refer to its execution of line 19-20 of Procedure 6.

**Definition 6.6** For a dequeue, **slot-scan phase** refer to its execution of line 24-34 of Procedure 7.

**Definition 6.7** An enqueue operation e is said to **match** a dequeue operation d if d returns a timestamp that e enqueues. Similarly, d is said to **match** e. In this case, both e and d are said to be **matched**.

**Definition 6.8** An enqueue operation e is said to be **unmatched** if no dequeue operation **matches** it.

**Definition 6.9** A dequeue operation d is said to be **unmatched** if no enqueue operation **matches** it, in other word, d returns  $\bot$ .

We prove some algorithm-specific results first, which will form the basis for the more fundamental results.

**Lemma 6.1** If an enqueue e begins its **slot-refresh phase** at time  $t_0$  and finishes at time  $t_1$ , there's always at least one successful

refreshEnqueue that either doesn't execute its CAS-sequence or starts and ends its CAS-sequence between  $t_0$  and  $t_1$  or a successful refreshDequeue on rank(e) starting and ending its CAS-sequence between  $t_0$  and  $t_1$ .

**Proof** If one of the two refreshEnqueues succeeds, then the lemma obviously holds.

Consider the case where both fail.

The first refreshEnqueue fails because it tries to execute its **CAS-sequence** but there's another refreshDequeue executing its **slot-modification** instruction successfully after  $t_0$  but before the end of the first refreshEnqueue's **CAS-sequence**.

The second refreshEnqueue fails because it tries to execute its CAS-sequence but there's another refreshDequeue executing its slot-modification instruction successfully after  $t_0$  but before the end of the second refreshEnqueue's CAS-sequence. This another refreshDequeue must start its CAS-sequence after the end of the first successful refreshDequeue, due to Lemma 5.2.1. In other words, this another refreshDequeue starts and successfully ends its CAS-sequence between  $t_0$  and  $t_1$ .

We have proved the theorem.  $\Box$ 

**Lemma 6.2** If a dequeue d begins its **slot-refresh phase** at time  $t_0$  and finishes at time  $t_1$ , there's always at least one successful refreshEnqueue or refreshDequeue on rank(d) starting and ending its **CAS-sequence** between  $t_0$  and  $t_1$ .

**Proof** This is similar to the above lemma.

**Lemma 6.3** Given a rank r, if an enqueue e on r that obtains the timestamp c completes at  $t_0$  and is still unmatched by  $t_1$ , then  $slot(r,t) \leq c$  for any  $t \in [t_0,t_1]$ .

**Proof** Take t' to be the time e's spsc\_enqueue takes effect.

At some point after t', e must enter its **slot-refresh phase**. By Lemma 6.1, there must be a successful refresh call after t'. If this refresh call

executes a **CAS-sequence** at  $t'' \geq t'$ ,  $t'' \in [t', t_0]$ , this **CAS-sequence** must observe the effect of spsc\_enqueue. Therefore,  $slot(r, t'') \leq c$ . If this refresh call doesn't execute a **CAS-sequence**, it must be a refreshEnqueue seeing that the front timestamp is different from the enqueued timestamp at t'',  $t'' \in [t', t_0]$ . Because e is unmatched up until  $t_1$  and due to Lemma 5.2.2,  $slot(r, t'') \leq c$ .

By the same reasoning as in Theorem 5.2.6, any successful slot-modification instructions happening after t'' must observe the effect of e's spsc\_enqueue. However, because e is never matched between t'' and  $t_1$ , the timestamp c is in the local SPSC the whole timespan  $[t'', t_1]$ . Therefore, any slot-modification instructions during  $[t'', t_1]$  must set the slot's value to some value not greater than c.

We now look at the more fundamental results.

**Theorem 6.4** If an enqueue e precedes another dequeue d, then either:

- *d* isn't matched.
- d matches e.
- e matches d' and d' precedes d.
- d matches e' and e' precedes e.
- d matches e' and e' overlaps with e.

**Proof** If d doesn't match anything, the theorem holds. If d matches e, the theorem also holds. Suppose d matches e',  $e' \neq e$ .

If e matches d' and d' precedes d, the theorem also holds. Suppose e matches d' such that d precedes d' or is unmatched. (1)

Suppose e obtains a timestamp of c and e' obtains a timestamp of c'.

Due to (1), at the time d starts, e has finished but it is still unmatched. By the way Procedure 7 is defined and by Lemma 6.3, d would find a slot that stores a timestamp that is not greater than the one e enqueues. In other word,  $c' \leq c$ . But  $c' \neq c$ , then c' < c. Therefore, e cannot precede e', otherwise, c < c'.

So, either e' precedes or overlaps with e. The theorem holds.

**Lemma 6.5** If d matches e, then either e precedes or overlaps with d.

**Proof** If d precedes e, none of the local SPSCs can contain an item with the timestamp of e. Therefore, d cannot return an item with a timestamp of e. Thus d cannot match e.

Therefore, e either precedes or overlaps with d.  $\square$ 

**Theorem 6.6** If a dequeue d precedes another enqueue e, then either:

- *d* isn't matched.
- d matches e' such that e' precedes or overlaps with e and e' ≠ e.

**Proof** If *d* isn't matched, the theorem holds.

Suppose d matches e'. By Lemma 6.5, either e' precedes or overlaps with d. Therefore,  $e' \neq e$ . Furthermore, e cannot precede e', because then d would precede e'.

We have proved the theorem.  $\Box$ 

**Theorem 6.7** If an enqueue  $e_0$  precedes another enqueue  $e_1$ , then either:

- Both  $e_0$  and  $e_1$  aren't matched.
- $e_0$  is matched but  $e_1$  is not matched.
- $e_0$  matches  $d_0$  and  $e_1$  matches  $d_1$  such that  $d_0$  precedes  $d_1$ .

**Proof** If  $e_1$  is not matched, the theorem holds.

Suppose  $e_1$  matches  $d_1$ . By Lemma 6.5, either  $e_1$  precedes or overlaps with  $d_1$ .

Suppose the contrary,  $e_0$  is unmatched or  $e_0$  matches  $d_0$  such that  $d_1$  precedes  $d_0$ , then when  $d_1$  starts,  $e_0$  is still unmatched.

If  $e_0$  and  $e_1$  targets the same rank, it's obvious that  $d_1$  must prioritize  $e_0$  over  $e_1$ . Thus  $d_1$  cannot match  $e_1$ .

If  $e_0$  targets a later rank than  $e_1$ ,  $d_1$  cannot find  $e_1$  in the first scan, because the scan is left-to-right, and if it finds  $e_1$  it would later find  $e_0$  that has a lower timestamp. Suppose  $d_1$  finds  $e_1$  in the

second scan, that means  $d_1$  finds  $e' \neq e_1$  and e''s timestamp is larger than  $e_1$ 's, which is larger than  $e_0$ 's. Due to the scan being left-to-right, e' must target a later rank than  $e_1$ . If e' also targets a later rank than  $e_0$ , then in the second scan,  $d_1$  would have prioritized  $e_0$  that has a lower timestamp. Suppose e' targets an earlier rank than  $e_0$  but later than  $e_1$ . Because  $e_0$ 's timestamp is larger than e''s, it must precede or overlap with e. Similarlt,  $e_1$  must precede or overlap with e. Because e' targets an earlier rank than  $e_0$ ,  $e_0$ 's slot-refresh phase must finish after e''s. That means  $e_1$  must start after e''s slot-refresh phase, because  $e_0$  precedes  $e_1$ . But then,  $e_1$  must obtain a timestamp larger than e', which is a contradiction.

Suppose  $e_0$  targets an earlier rank than  $e_1$ . If  $d_1$  finds  $e_1$  in the first scan, than in the second scan,  $d_1$  would have prioritize  $e_0$ 's timestamp. Suppose  $d_1$  finds  $e_1$  in the second scan and during the first scan, it finds  $e' \neq e_1$  and e''s timestamp is larger than  $e_1$ 's, which is larger than  $e_0$ 's. Due to how the second scan is defined, e' targets a later rank than  $e_1$ , which targets a later rank than  $e_0$ . Because during the second scan,  $e_0$  is not chosen, its **slot-refresh phase** must finish after e''s. Because  $e_0$  preceds  $e_1$ ,  $e_1$  must start after e''s **slot-refresh phase**, so it must obtain a larger timestamp than e', which is a contradiction.

Therefore, by contradiction,  $e_0$  must be matched and  $e_0$  matches  $d_0$  such that  $d_0$  precedes  $d_1$ .  $\square$ 

**Theorem 6.8** If a dequeue  $d_0$  precedes another dequeue  $d_1$ , then either:

- $d_0$  isn't matched.
- $d_1$  isn't matched.
- d<sub>0</sub> matches e<sub>0</sub> and d<sub>1</sub> matches e<sub>1</sub> such that e<sub>0</sub>
  precedes or overlaps with e<sub>1</sub>.

**Proof** If either  $d_0$  isn't matched or  $d_1$  isn't matched, the theorem holds.

Suppose  $d_0$  matches  $e_0$  and  $d_1$  matches  $e_1$ .

If  $e_1$  precedes  $e_0$ , applying Theorem 6.7, we have  $e_1$  matches  $d_1$  and  $e_0$  matches  $d_0$  such that  $d_1$  precedes  $d_0$ . This is a contradiction.

Therefore,  $e_0$  either precedes or overlaps with  $e_1$ .  $\Box$ 

**Theorem 6.9** (*Linearizability of Slot-queue*) Slot-queue is linearizable.

**Proof** Suppose some history H produced from the Slot-queueu algorithm.

If H contains some pending method calls, we can just wait for them to complete (because the algorithm is wait-free, which we will prove later). Therefore, now we consider all H to contain only completed method calls. So, we know that if a dequeue or an enqueue in H is matched or not.

If there are some unmatched enqueues, we can append dequeues sequentially to the end of H until there's no unmatched enqueues. Consider one such H'.

We already have a strict partial order  $\rightarrow_{H'}$  on H'.

Because the queue is MPSC, there's already a total order among the dequeues.

We will extend  $\rightarrow_{H'}$  to a strict total order  $\Rightarrow_{H'}$  on H' as follows:

- If  $X \to_{H'} Y$  then  $X \Rightarrow_{H'} Y$ . (1)
- If a dequeue d matches e then  $e \Rightarrow_{H'} d$ . (2)
- If a dequeue  $d_0$  matches  $e_0$  and another dequeue matches  $e_1$  such that  $d_0\Rightarrow_{H'}\!d_1$  then  $e_0\Rightarrow_{H'}\!e_1$ . (3)
- If a dequeue d overlaps with an enqueue e but does not match e,  $d \Rightarrow_{H'} e$ . (4)

We will prove that  $\Rightarrow_{H'}$  is a strict total order on H'. That is, for every pair of different method calls X and Y, either exactly one of these is true  $X \Rightarrow_{H'} Y$  or  $Y \Rightarrow_{H'} X$  and for any  $X, X \not\Rightarrow_{H'} X$ .

It's obvious that  $X \not\Rightarrow_{H'} X$ .

If X and Y are dequeues, because there's a total order among the dequeues, either exactly one of these is true:  $X \to_{H'} Y$  or  $Y \to_{H'} X$ . Then due to (1), either  $X \Rightarrow_{H'} Y$  or  $Y \Rightarrow_{H'} X$ . Notice that we cannot obtain  $X \Rightarrow_{H'} Y$  or  $Y \Rightarrow_{H'} X$  from (2), (3), or (4).

Therefore, exactly one of  $X \Rightarrow_{H'} Y$  or  $Y \Rightarrow_{H'} X$  is true. (\*)

If X is dequeue and Y is enqueue, in this case (3) cannot help us obtain either  $X \Rightarrow_{H'} Y$  or  $Y \Rightarrow_{H'} X$ , so we can disregard it.

- If  $X \to_{H'} Y$ , then due to (1),  $X \Rightarrow_{H'} Y$ . By definition, X precedes Y, so (4) cannot apply. Applying Theorem 6.6, either
  - X isn't matched, (2) cannot apply. Therefore,  $Y \not\Rightarrow_{H'} X$ .
  - X matches e' and  $e' \neq Y$ . Therefore, X does not match Y, or (2) cannot apply. Therefore,  $Y \not\Rightarrow_{H'} X$ .

Therefore, in this case,  $X \Rightarrow_{H'} Y$  and  $Y \not\Rightarrow_{H'} X$ .

- If  $Y \to_{H'} X$ , then due to (1),  $Y \Rightarrow_{H'} X$ . By definition, Y precedes X, so (4) cannot apply. Even if (2) applies, it can only help us obtain  $Y \Rightarrow_{H'} X$ . Therefore, in this case,  $Y \Rightarrow_{H'} X$  and  $X \not\Rightarrow_{H'} Y$ .
- If *X* overlaps with *Y*:
  - If X matches Y, then due to (2),  $Y \Rightarrow_{H'} X$ . Because X matches Y, (4) cannot apply. Therefore, in this case  $Y \Rightarrow_{H'} X$  but  $X \not\Rightarrow_{H'} Y$ .
  - If X does not match Y, then due to (4),  $X \Rightarrow {}_{H'}Y$ . Because X doesn't match Y, (2) cannot apply. Therefore, in this case  $X \Rightarrow_{H'} Y$  but  $Y \not\Rightarrow_{H'} X$ .

Therefore, exactly one of  $X \Rightarrow_{H'} Y$  or  $Y \Rightarrow_{H'} X$  is true. (\*\*)

If X is enqueue and Y is enqueue, in this case (2) and (4) are irrelevant:

- If  $X \to_{H'} Y$ , then due to (1),  $X \Rightarrow_{H'} Y$ . By definition, X precedes Y. Applying Theorem 6.7,
  - Both X and Y aren't matched, then (3) cannot apply. Therefore, in this case, Y ⇒<sub>H'</sub>X.
  - X is matched but Y is not matched, then (3) cannot apply. Therefore, in this case,  $Y \not\Rightarrow_{H'} X$ .
  - X matches  $d_x$  and Y matches  $d_y$  such that  $d_x$  precedes  $d_y$ , then (3) applies and we obtain  $X \Rightarrow_{H'} Y$ .

Therefore, in this case,  $X \Rightarrow_{H'} Y$  but  $Y \not\Rightarrow_{H'} X$ .

- If Y →<sub>H'</sub>X, this case is symmetric to the first case. We obtain Y ⇒<sub>H'</sub>X but X ⇒<sub>H'</sub>Y.
- If X overlaps with Y, because in H', all enqueues are matched, then, X matches  $d_x$  and  $d_y$ . Because  $d_x$  either precedes or succeeds  $d_y$ , Applying (3), we obtain either  $X \Rightarrow_{H'} Y$  or  $Y \Rightarrow_{H'} X$  and there's no way to obtain the other.

Therefore, exactly one of  $X \Rightarrow_{H'} Y$  or  $Y \Rightarrow_{H'} X$  is true. (\*\*\*)

From (\*), (\*\*), (\*\*), we have proved that  $\Rightarrow_{H'}$  is a strict total ordering that is consistent with  $\rightarrow$   $_{H'}$ . In other words, we can order method calls in H' in a sequential manner. We will prove that this sequential order is consistent with FIFO semantics:

- An item can only be dequeued once: This is trivial as a dequeue can only match one enqueue.
- Items are dequeued in the order they are enqueued: Suppose there are two enqueues  $e_1, e_2$  such that  $e_1 \Rightarrow_{H'} e_2$  and suppose they match  $d_1$  and  $d_2$ . Then we have obtained  $e_1 \Rightarrow_{H'} e_2$  either because:
  - (3) applies, in this case  $d_1 \Rightarrow_{H'} d_2$  is a condition for it to apply.
  - (1) applies, then  $e_1$  precedes  $e_2$ , by Theorem 6.7,  $d_1$  must precede  $d_2$ , thus  $d_1 \Rightarrow \frac{1}{d_2}$ .

Therefore, if  $e_1 \Rightarrow_{H'} e_2$  then  $d_1 \Rightarrow_{H'} d_2$ .

- An item can only be dequeued after it's enqueued: Suppose there is an enqueue e matched by d. By (2), obviously  $e \Rightarrow_{H'} d$ .
- If the queue is empty, dequeues return nothing. Suppose a dequeue d such that any  $e \Rightarrow_{H'} d$  is all matched by some d' and  $d' \Rightarrow_{H'} d$ , we will prove that d is unmatched. By Lemma 6.5, d can only match an enqueue  $e_0$  that precedes or overlaps with d.
  - If e<sub>0</sub> precedes d, by our assumption, it's already matched by another dequeue.
  - If  $e_0$  overlaps with d, by our assumption,  $d \Rightarrow H'e_0$  because if  $e_0 \Rightarrow_{H'} d$ ,  $e_0$  is already matched by another d'. Then, we can only obtain this because (4) applies, but then d does not match  $e_0$ .

Therefore, d is unmatched.

In conclusion,  $\Rightarrow_{H'}$  is a way we can order method calls in H' sequentially that conforms to FIFO semantics. Therefore, we can also order method calls in H sequentially that conforms to FIFO semantics as we only append dequeues sequentially to the end of H to obtain H'.

We have proved the theorem.

#### 7. Wait-freedom

The algorithm is trivially wait-free as there is no possibility of infinite loops.

## 8. Memory-safety

The algorithm is memory-safe: No memory deallocation happens and accesses are only made on allocated memory.
